Approximation algorithm for problem P :

- I : Instance of problem P
- $A(I)$: value of A 's solution on I
- $OPT(I)$: value of the optimal solution on I
- A is r -approximate if
 - ◆ **Minimization:** $\forall I, A(I) \leq r \times OPT(I)$
 - ◆ **Maximization:** $\forall I, A(I) \geq \frac{1}{r} \times OPT(I)$

Relate to the Optimum

- Randomized Rounding

- The optimum may be hard to compute or to characterize
- However in some cases we can relate to the optimum, e.g., Christofides

$$\underline{ALG(I)} \leq \underline{MST(I) + \text{Matching}(I)} \leq \left(1 + \frac{1}{2}\right) OPT(I)$$

Relate to the optimum of a relaxed problem:

$$OPT(I) = \min_{x \in S(I)} f(x)$$

Relaxation: $S(I) \subseteq R(I)$

$$LB(I) = \min_{x \in R(I)} g(x)$$

$$\forall I, x \in S(I), g(x) \leq f(x)$$

Use the solution of the relaxed problem

- The Primal-Dual Method

- Primal-dual Method for Vertex Cover

- Set Cover via Dual Lifting

- Randomized Rounding

If $\forall I, ALG(I) \leq r \times \underline{LB(I)}$
then $\forall I, ALG(I) \leq r \times OPT(I)$

Optimum of $LB(I)$:

$$x^* : g(x^*) = \min_{x \in R(I)} g(x)$$

The optimum to the relaxed problem must be easy to compute.

Rounding:

Round x^* to a $\bar{x} \in S(I)$: $f(\bar{x}) \leq r \times g(x^*)$

LP formulation for Vertex Cover

- Primal-dual Method for Vertex Cover

- Set Cover via Dual Lifting

- Randomized Rounding

$$\min \sum_{v \in V} x(v)w(v)$$

$$\text{s.t. } \begin{aligned} x(u) + x(v) &\geq 1 & \forall (u, v) \in E \\ x(u) &\in [0, 1] & u \in V \end{aligned}$$

- The fractional LP program can be computed in polynomial time
- All vertex covers are still feasible solution to the LP relaxation
- The optimum to the LP relaxation is a lower bound to the optimum vertex cover

Rounding

- Lecture Outline

- The Primal-Dual Method

- Primal-dual Method for Vertex Cover

- Set Cover via Dual Lifting

- Randomized Rounding

■ Find an optimal solution $x^* \in R$ to the relaxed problem in polynomial time

■ Round $x^* \in R$ to a $\bar{x} \in S$

$$\begin{aligned} \blacklozenge \quad & \bar{x}(u) = 1 \text{ if } x^*(u) \geq \frac{1}{2} \\ \blacklozenge \quad & \bar{x}(u) = 0 \text{ if } x^*(u) < \frac{1}{2} \end{aligned}$$

■ The solution \bar{x} is feasible:

$$\forall e = (u, v), \bar{x}(u) + \bar{x}(v) \geq 1$$

since either $x^*(u) \geq \frac{1}{2}$ or $x^*(v) \geq \frac{1}{2}$

Approximation

Definition: largest ratio on all instances between the optimum integral solution and the optimum relaxed solution.

One cannot hope to achieve an approximation ratio better than the integrality gap of the relaxation

The rounding step should pay a factor at least equal to the integrality gap of the relaxation

Integrality Gap for Vertex Cover

- Primal-dual Method for Vertex Cover

- Set Cover via Dual Lifting

- Randomized Rounding

- On a clique graph the optimal vertex cover is of size $n - 1$
- $x^*(u) = \frac{1}{2}$ is a feasible fractional solution of value $n/2$
- The integrality gap is equal to $2 \left(1 - \frac{1}{n}\right)$
- It is not possible to prove better than 2 approximation for Vertex Cover with this LP

Let $f = \max_{e \in U} |\{S \in \mathcal{S} | e \in S\}|$

1. Round to 1 all variables $x(S) \geq \frac{1}{f}$
2. The solution is feasible since every element appears in at least one set with $x(S) \geq \frac{1}{f}$
3. $ALG \leq f \times OPT^{LP}$

For Vertex cover we have $f = 2$.

An $O(\log n)$ approximation algorithm for Weighted Set Cover will follow in this lecture

- The Primal-Dual Method

- Primal-dual Method for Vertex Cover

- Set Cover via Dual Lifting

- Randomized Rounding

- Primal-dual scheme: consider the dual of a relaxation of the problem:

$$\max\{h(y) : y \in D\} \leq \min\{g(x) : x \in R\}$$

Construct a feasible solution $x \in S$ for the primal from $y \in D$ such that

$$f(x) \leq r \times h(y) \leq r \times h(y^*) \leq r \times f(x^*) \leq r \times OPT$$

- Use Randomization in the rounding step: Interpret x^* as a set of probabilistic values to guide the rounding step. E.g., $\bar{x}(u) = 1$ with pb $x^*(u)$.
- Use different relaxations: e.g., semi-definite programming relaxations

Assume U covered by Greedy in order $\{e_1, \dots, e_n\}$

Lemma 5 $price(e_j) \leq \frac{OPT}{n-j+1}$

Proof:

- At any iteration the optimal solution covers C_i at cost at most OPT
- There exists a set of OPT with $\alpha \leq \frac{OPT}{C_i}$
- When e_j is covered at iteration i , $C_i \geq n - j + 1$
- Since e_j is covered by the most cost-effective set:

$$price(e_j) \leq \frac{OPT}{C_i} \leq \frac{OPT}{n-j+1}$$

□

Theorem 6

$$ALG = \sum_{j=1}^n price(e_j) \leq OPT \times \sum_{j=1}^n \frac{1}{n-j+1} = OPT \times H_n$$

A tight example for Greedy

Greedy outputs all singleton sets with cost

$$H_n = 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n}$$

Optimum cost is $1 + \epsilon$.

Dual-fitting method:

- Show that the integral solution is fully paid by an unfeasible dual solution
- The dual solution can be made feasible by scaling down each variable by a factor f

$$ALG = \underline{DUAL^{unf}} = \underline{f \times DUAL^{feas}} \leq \underline{f \times OPT^{LP}} \leq \underline{f \times OPT}$$

- Alternative to argue about complementary slackness conditions

Interpret the Greedy solution as an unfeasible dual:

$$y(e) = \text{price}(e), \text{ALG} = \sum_{e \in U} y(e)$$

Lemma 7 $y'(e) = \frac{\text{price}(e)}{H_n}$ is dual feasible.

- Consider any set $S = \{e_1, \dots, e_k\}$ with elements numbered by the order they are covered by Greedy.

- S can cover e_i at price $\leq \frac{c(S)}{k-i+1}$ when i is covered.

- Since Greedy picks the most cost-effective set:

$$\text{price}(e_i) \leq \frac{c(S)}{k-i+1}$$

- Dual variables $y'(e) \leq \frac{1}{H_n} \frac{c(S)}{k-i+1}$

- Dual constraint for set S :

$$\sum_{i=1}^k y'(e_i) \leq \frac{c(S)}{H_n} \left(\frac{1}{k} + \frac{1}{k-1} + \dots + 1 \right) = c(S) \frac{H_k}{H_n} \leq c(S)$$
