

Exercise on cache,
miss, hit etc.

XV_Analysis of Design alternatives for reverse proxy cache providers

Modeling and evaluation

Reverse proxy cache geographically distributed,
organized in a hierarchical manner, have limited customers,
are implemented over cluster of workstation and
are connected through a VPN to the WS.

Request management

- Proxy configuration: no global memory management
- Cache content defined by access pattern (object popularity)

Architecture

- Advantages:
reduce load
Improve THP
Reduce latency
Multiple sites
share infrastructure.

Nomenclature

WS_k	k-th Web site
$C_{WS_k}^T$	total RAM capacity of WS_k
λ_k	arrival rate of HTTP requests to WS_k
n_k	total number of cacheable objects associated with WS_k
α_k	parameter of the Zipf-like distribution associated with WS_k
$p_{k,j}$	relative popularity of the j-th cacheable object of WS_k
$\mu_{k,j}$	update rate of the j-th cacheable object of WS_k
$\lambda_{k,j}^{CN}$	request arrival rate, associated with WS_k , seen by any single cache node
C_{tot}^{CN}	total cache node RAM capacity
C_k	cache node RAM capacity destined to cacheable objects of WS_k
M_{R_k}	miss ratio within the cache node RAM/disk for requests associated with WS_k
$R_{H_{R_k}}$	cache node RAM hit ratio for cacheable objects of WS_k
$D_{H_{R_k}}$	cache node disk hit ratio for cacheable objects of WS_k
N	total number of Web sites hosted by a cache node
NP	total number of Proxy sites
NCN_k	number of cache nodes within a Proxy site that are assigned to WS_k

The model has real constraints:

- bounded cache size and processing power
- popularity and update rates of the documents

It permits identification of archit. depending on:

- Resource assign policy
- Workload characteristics

Also ident of state and transient behavior of the arch.
