Introduction to **Information Retrieval**

CS276
Information Retrieval and Web Search
Chris Manning and Pandu Nayak

Personalization

Ambiguity

- Unlikely that a short query can unambiguously describe a user's information need
- For example, the query [chi] can mean
 - Calamos Convertible Opportunities & Income Fund quote
 - The city of Chicago
 - Balancing one's natural energy (or ch'i)
 - Computer-human interactions

Personalization

- Ambiguity means that a single ranking is unlikely to be optimal for all users
- Personalized ranking is the only way to bridge the gap
- Personalization can use
 - Long term behavior to identify user interests,
 e.g., a long term interest in user interface research
 - Short term session to identify current task,
 e.g., checking on a series of stock tickers
 - User location, e.g., MTA in New York vs Baltimore
 - Social network
 - **-** ...

Potential for Personalization

[Teevan, Dumais, Horvitz 2010]

•How much can personalization improve ranking? How can we measure this?

- Ask raters to explicitly rate a set of queries
 - But rather than asking them to guess what a user's information need might be ...
 - ... ask which results they would personally consider relevant
 - Use self-generated and pre-generated queries

Computing potential for personalization

- For each query q
 - Compute average rating for each result
 - Let R_q be the optimal ranking according to the average rating
 - Compute the NDCG value of ranking R_q for the ratings of each rater i
 - Let Avg_q be the average of the NDCG values for each rater
- Let Avg be the average Avg_q over all queries
- Potential for personalization is (1 Avg)

Example: NDCG values for a query

| Result | Rater A | Rater B | Average rating |
|--------|---------|---------|----------------|
| D1 | 1 | 0 | 0.5 |
| D2 | 1 | 1 | 1 |
| D3 | 0 | 1 | 0.5 |
| D4 | 0 | 0 | 0 |
| D5 | 0 | 0 | 0 |
| D6 | 1 | 0 | 0.5 |
| D7 | 1 | 2 | 1.5 |
| D8 | 0 | 0 | 0 |
| D9 | 0 | 0 | 0 |
| D10 | 0 | 0 | 0 |
| NDCG | 0.88 | 0.65 | |

Average NDCG for raters: 0.77

Example: NDCG values for optimal ranking for average ratings

| Result | Rater A | Rater B | Average rating |
|--------|---------|---------|----------------|
| D7 | 1 | 2 | 1.5 |
| D2 | 1 | 1 | 1 |
| D1 | 1 | 0 | 0.5 |
| D3 | 0 | 1 | 0.5 |
| D6 | 1 | 0 | 0.5 |
| D4 | 0 | 0 | 0 |
| D5 | 0 | 0 | 0 |
| D8 | 0 | 0 | 0 |
| D9 | 0 | 0 | 0 |
| D10 | 0 | 0 | 0 |
| NDCG | 0.98 | 0.96 | |

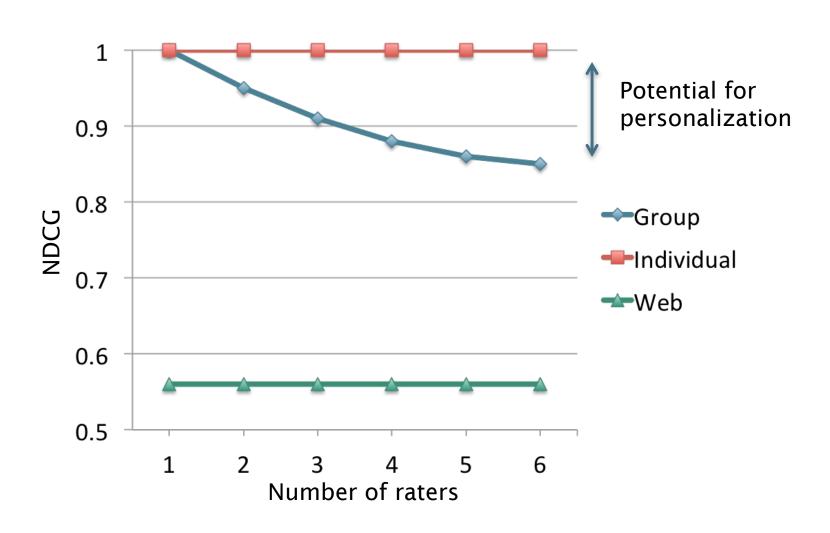

Average NDCG for raters: 0.97

Example: Potential for personalization

| Result | Rater A | Rater B | Average rating |
|--------|---------|---------|----------------|
| D7 | 1 | 2 | 1.5 |
| D2 | 1 | 1 | 1 |
| D1 | 1 | 0 | 0.5 |
| D3 | 0 | 1 | 0.5 |
| D6 | 1 | 0 | 0.5 |
| D4 | 0 | 0 | 0 |
| D5 | 0 | 0 | 0 |
| D8 | 0 | 0 | 0 |
| D9 | 0 | 0 | 0 |
| D10 | 0 | 0 | 0 |
| NDCG | 0.98 | 0.96 | |

Potential for personalization: 0.03

Potential for personalization graph

PERSONALIZING SEARCH

Personalizing search

[Pitkow et al. 2002]

- Two general ways of personalizing search
 - Query expansion
 - Modify or augment user query
 - E.g., query term "IR" can be augmented with either "information retrieval" or "Ingersoll-Rand" depending on user interest
 - Ensures that there are enough personalized results

Reranking

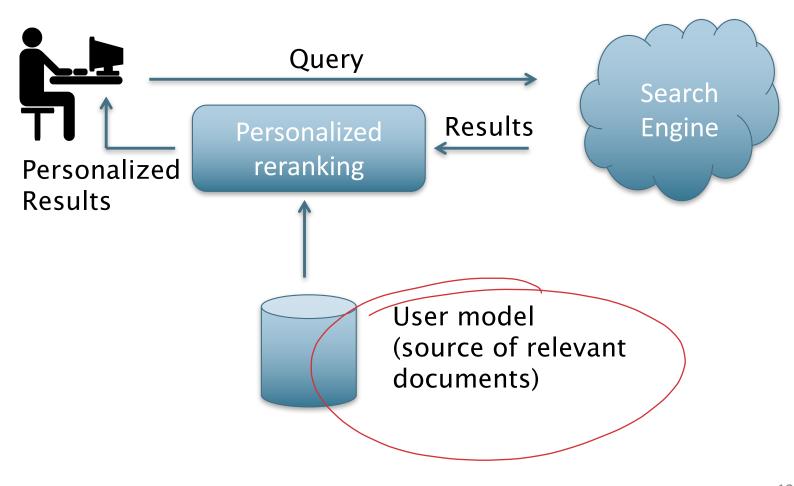

- Issue the same query and fetch the same results ...
- ... but rerank the results based on a user profile
- Allows both personalized and globally relevant results

User interests

- Explicitly provided by the user
 - Sometimes useful, particularly for new users
 - ... but generally doesn't work well
- Inferred from user behavior and content
 - Previously issued search queries
 - Previously visited Web pages
 - Personal documents
 - Emails
- Ensuring privacy and user control is very important

Relevance feedback perspective

[Teevan, Dumais, Horvitz 2005]

Binary Independence Model

Estimating RSV coefficients in theory

$$c_i = \log \frac{p_i(1-r_i)}{r_i(1-p_i)}$$

• For each term i look at this table of document counts:

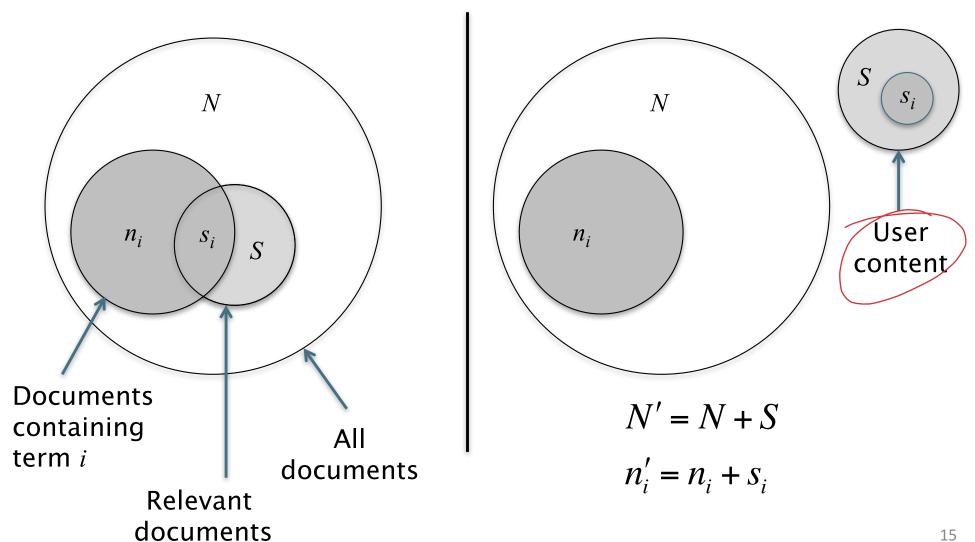

| Documents | Relevant | Non-Relevant | Total |
|-----------|-------------|---------------|-------------|
| | | | |
| $x_i=1$ | S_i | n_i - S_i | n_i |
| $x_i=0$ | S - s_i | $N-n_i-S+s_i$ | N - n_i |
| Total | S | N-S | N |

• Estimates:
$$p_i \approx \frac{s_i}{S}$$
 $r_i \approx \frac{(n_i - s_i)}{(N - S)}$

$$c_i \approx K(N, n_i, S, s_i) = \log \frac{s_i/(S - s_i)}{(n_i - s_i)/(N - n_i - S + s_i)}$$

For now, assume no zero terms. See later lecture.

Personalization as relevance feedback

Reranking

BM25 scoring

$$\sum c_i \times tf_i$$

• Use updated weight c_i in BM25

$$c_i = \log \frac{(s_i + 0.5)}{(S - s_i + 0.5)} \frac{(N - n_i + 0.5)}{(n_i + 0.5)} \approx \log \frac{(s_i + 0.5)}{(S - s_i + 0.5)} + IDF_i$$

where we have used

$$N' = N + S$$

$$n_i' = n_i + S_i$$

Corpus representation

- Estimating N and n_i
- Many possibilities
 - N: All documents, query relevant documents, result set
 - n_i : Full text, only titles and snippets
- Practical strategy
 - Approximate corpus statistics from result set
 - ... and just the title and snippets
 - Empirically seems to work the best!

User representation

- Estimating S and s_i
- Estimated from a local search index containing
 - Web pages the user has viewed
 - Email messages that were viewed or sent
 - Calendar items
 - Documents stored on the client machine

- Best performance when
 - S is the number of local documents matching the query
 - s_i is the number that also contains term i

Document and query representation

- Document represented by the title and snippets
- Query is expanded to contain words near query terms (in titles and snippets)
 - For the query [cancer] add underlined terms

The <u>American Cancer Society</u> is dedicated to <u>eliminating</u> cancer as a <u>major</u> health problem by <u>preventing</u> cancer, <u>saving</u> lives, and diminishing suffering through ...

 This combination of corpus, user, document, and query representations seem to work well

LOCATION

User location

- User location is one of the most important features for personalization
 - Country
 - Query [football] in the US vs the UK
 - State/Metro/City
 - Queries like [zoo], [craigslist], [giants]
 - Fine-grained location
 - Queries like [pizza], [restaurants], [coffee shops]

Challenges

- Not all queries are location sensitive
 - [facebook] is not asking for the closest Facebook office
 - [seaworld] is not necessarily asking for the closest SeaWorld
- Different parts of a site may be more or less location sensitive
 - NYTimes home page vs NYTimes Local section
- Addresses on a page don't always tell us how location sensitive the page is
 - Stanford home page has address, but not location sensitive

Key idea

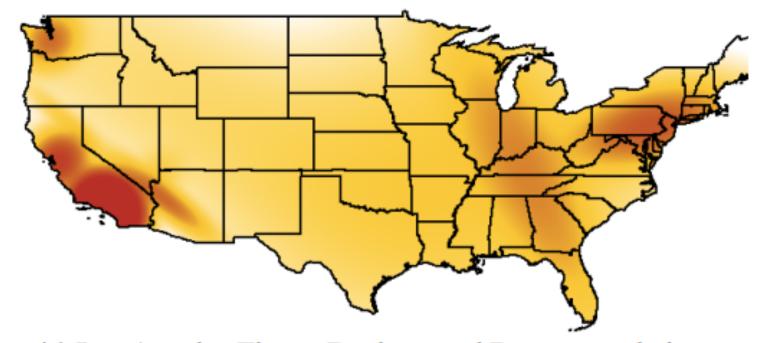

[Bennett et al. 2011]

- Usage statistics, rather than locations mentioned in a document, best represent where it is relevant
 - I.e., if users in a location tend to click on that document,
 then it is relevant in that location
- User location data is acquired from anonymized logs (with user consent, e.g., from a widely distributed browser extension)
 - User IP addresses are resolved into geographic location information

Location interest model

 Use the logs data to estimate the probability of the location of the user given they viewed this URL

$$P(location = x | URL)$$

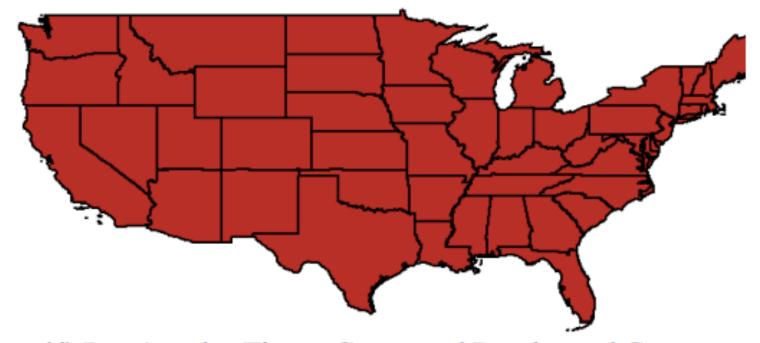

(c) Los Angeles Times: Reviews and Recommendations http://findlocal.latimes.com/

Location interest model

 Use the logs data to estimate the probability of the location of the user given they viewed this URL

$$P(location = x | URL)$$

(d) Los Angeles Times: Crossword Puzzles and Games http://games.latimes.com/

Learning the location interest model

 For compactness, represent location interest model as a mixture of 5-25 2-d Gaussians (x is [lat, long])

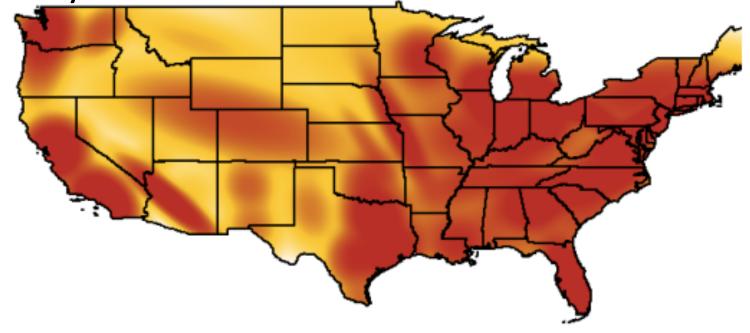

$$P(location = x \mid URL) = \sum_{i=1}^{n} w_i N(x; \mu_i, \sum_i)$$

$$= \sum_{i=1}^{n} \frac{w_i}{(2\pi)^2 |\Sigma_i|^{1/2}} e^{-\frac{1}{2}(x-\mu_i)^T \Sigma_i^{-1}(x-\mu_i)}$$

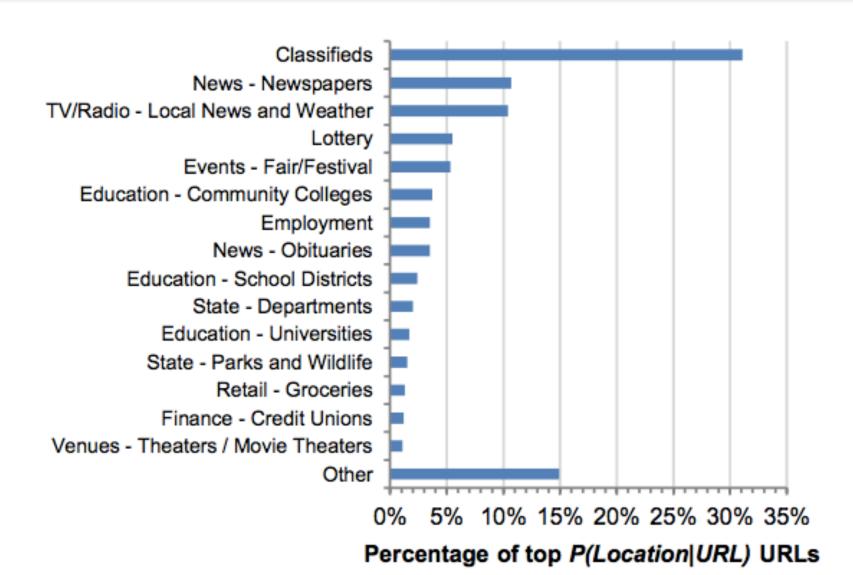

- Learn Gaussian mixture model using EM
 - Expectation step: Estimate probability that each point belongs to each Gaussian
 - Maximization step: Estimate most likely mean, covariance, weight

More location interest models

- Learn a location-interest model for queries
 - Using location of users who issued the query
- Learn a background model showing the overall density of users

Topics in URLs with high P(user location | URL)

Location sensitive features

- Non-contextual features (user-independent)
 - Is the query location sensitive? What about the URLs?
 - Feature: Entropy of the location distribution
 - Low entropy means distribution is peaked and location is important
 - Feature: KL-divergence between location model and background model
 - High KL-divergence suggests that it is location sensitive
 - Feature: KL-divergence between query and URL models
 - Low KL-divergence suggests URL is more likely to be relevant to users issuing the query

More location sensitive features

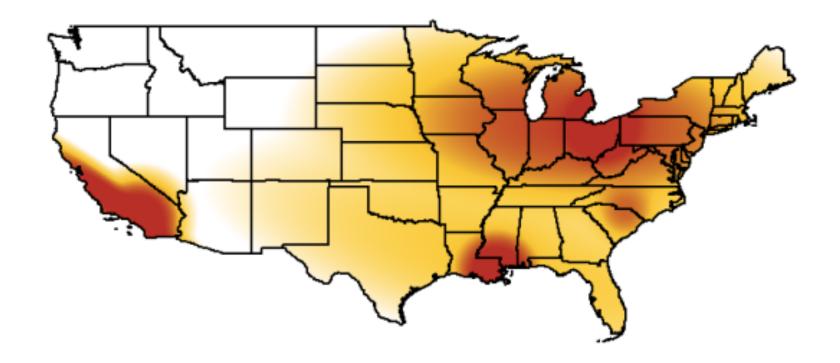

- Contextual features (user-dependent)
 - Feature: User's location (naturally!)
 - Feature: Probability of the user's location given the URL
 - Computed by evaluating URL's location model at user location
 - Feature is high when user is at a location where URL is popular
 - Downside: large population centers tend to higher probabilities for all URLs
 - Feature: Use Bayes rule to compute P(URL | user location)
 - Feature: Also create a normalized version of the above feature by normalizing with the background model
 - Features: Versions of the above with query instead of URL

Learning to rank

- Add location features (in addition to standard features) for machine learned ranking
 - Training data derived from logs
 - P(URL | user location) turns out to be an important feature
 - KL divergence of the URL model from the background model also plays an important role

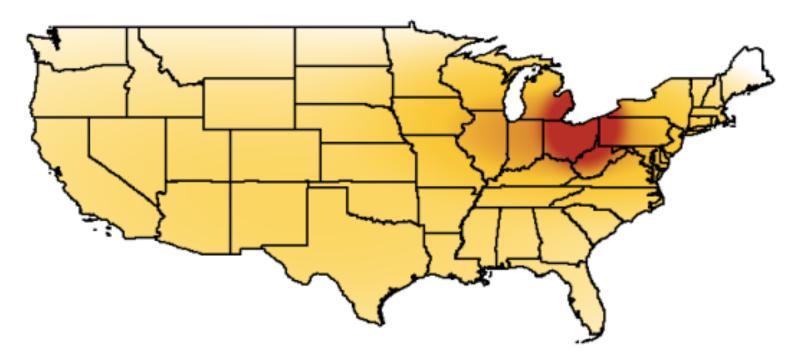

Query model for [rta bus schedule]

PERSONALIZED PAGERANK

Pagerank review

- Let A be the stochastic matrix corresponding to the
 Web graph G over n nodes
 - No teleportation links (but assume no deadends in G)
 - If node i has o_i outlinks, and there is an edge from node i to node j, then $\mathbf{A}_{ij} = 1/o_i$
- Let p be the teleportation probabilities
 - $(n \times 1)$ column vector with each entry being 1/n
- Pagerank vector r is defined by the following

$$\mathbf{r} = (1 - \alpha)\mathbf{A}\mathbf{r} + \alpha\mathbf{p}$$

Personalized pagerank

[Haveliwala 2003] [Jeh and Widom 2003]

- •In the basic pagerank computation, teleportation probability vector p is uniform over all pages
- But if the user has preferences on which pages to teleport to, that preference can be represented in p
 - p could be uniform over user's bookmarks
 - Or it could be non-zero on just pages on topics of interest to the user
- Pagerank would be personalized to user's interests
- But computing personalized pagerank is expensive

Linearity theorem

For any preference vectors $\mathbf{u_1}$ and $\mathbf{u_2}$, if $\mathbf{v_1}$ and $\mathbf{v_2}$ are the corresponding personalized pagerank vectors, then for any non-negative constants a_1 and a_2 such that $a_1 + a_2 = 1$, we have

$$a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2 = (1 - \alpha) \mathbf{A} (a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2) + \alpha (a_1 \mathbf{u}_1 + a_2 \mathbf{u}_2)$$

Proof

$$a_{1}\mathbf{v}_{1} + a_{2}\mathbf{v}_{2} = a_{1}((1-\alpha)\mathbf{A}\mathbf{v}_{1} + \alpha\mathbf{u}_{1}) + a_{2}((1-\alpha)\mathbf{A}\mathbf{v}_{2} + \alpha\mathbf{u}_{2})$$

$$= a_{1}(1-\alpha)\mathbf{A}\mathbf{v}_{1} + a_{1}\alpha\mathbf{u}_{1} + a_{2}(1-\alpha)\mathbf{A}\mathbf{v}_{2} + a_{2}\alpha\mathbf{u}_{2}$$

$$= (1-\alpha)\mathbf{A}(a_{1}\mathbf{v}_{1} + a_{2}\mathbf{v}_{2}) + \alpha(a_{1}\mathbf{u}_{1} + a_{2}\mathbf{u}_{2})$$

Topic-sensitive pagerank

- Compute personalized pagerank vector per topic
 - 16 top-level topics from the Open Directory Project
 - Each ODP topic has a set of pages (hand-)classified into that topic
 - Preference vector for the topic is uniform over pages in that topic, and 0 elsewhere

 Note: [Jeh and Widom 2003] provide a more general treatment

Query-time processing

- Construct a distribution over topics for the query
 - User profile can provide a distribution over topics
 - Query can be classified into the different topics
 - Any other context information can be used to inform topic distributions
- Use the topic preferences to compute a weighted linear combination of topic pagerank vectors to use in place of pagerank

SOCIAL NETWORKS

Unicorn

[Curtiss et al 2013]

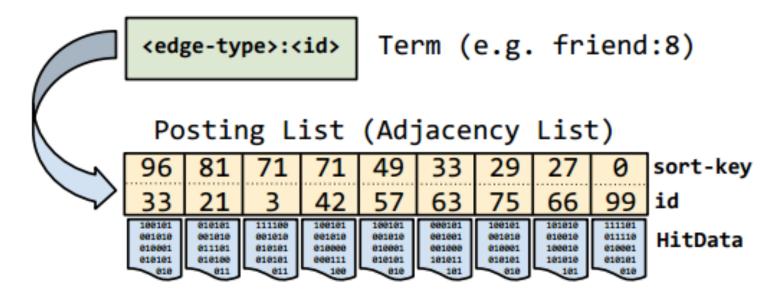

Primary backend for Facebook Graph Search

Facebook social graph

- Nodes represent people and things (entities)
- Each entity has a unique 64-bit id
- Edges represent relationships between nodes
- There are many thousands of edge-types
 - Examples: friend, likes, likers, ...

Data model

- Billions of nodes, but graph is sparse
 - Represent graph using adjacency list
 - Postings sorted by sort-key (importance) and then id
 - Index sharded by result-id

Basic set operations

- Query language includes basic set operations
 - and, or, difference
 - Friends of either Jon Jones (id 5) and Lea Lin (id 6) (or(friend:5 friend:6))
 - Female friends of Jon Jones who are not friend of Lea Lin (difference (and friend:5 gender:1) friend:6)

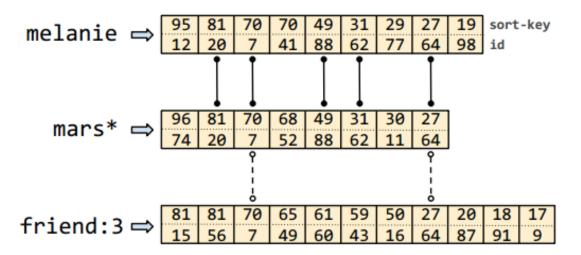

Typeahead

- Find users by typing first few characters of their name
- Index servers contain postings lists for every name prefix up to a predefined character limit
 - Simple typeahead implementation would simply return ids in the corresponding postings lists
- Simple solution doesn't ensure social relevance
- Alternate solution: Use a conjunctive query (and mel* friend:3)
 - Misses people who are not friends
 - Issuing two queries is expensive

WeakAnd operator

- Provides a mechanism for some fraction of results to possess a trait without requiring trait for all results
- WeakAnd allows missing terms from some results
 - These optional terms can have an optional count or weight
 - Once the optional count is met, the term is required

(weak-and (term friend: 3 : optional-hits 2) (term melanie) (term mars*))

Graph Search

- Graph Search results are often more than one edge away from source nodes
 - Example: Pages liked by friends of Melanie who like Emacs
- Unicorn provides additional operators to support Graph Search
 - Apply
 (apply likes: (and friend:7 likers:42))
 - Extract
 - Extract and return (denormalized) ids stored in HitData
